

ABSTRACT

A remote control system is provided that prevents a combination of a transmitter and a movable machine other than a combination determined in the system from being established, ensures fair fighting games, and is capable of easily discriminating a movable machine and a transmitter combined in the system even when combinations cannot be discriminated visibly.

A transmitter 2 reads characteristic information 10 from a recording medium 3 having the characteristic information associated with a movable machine 1 recorded thereon, and transmits the information to the movable machine 1 as initial data. If the received characteristic information coincides with characteristic information 16 the movable machine has, then the movable machine 1 comes in a state to ready to operate. Even if movable data destined to the movable machine 1 itself is transmitted, however, the movable machine 1 is not activated until the initial data containing the characteristic information 16 is received. The above described problem is solved by such a remote control system.
